The NSK Group is one of the world's leading manufacturers of rolling bearings, automotive components, precision and mechatronic products.

The Group has over 40 manufacturing units around the world, employing over 23,000 people and is represented by sales offices and Authorised Distributors almost everywhere.

This brochure outlines the range of standard RHP Super Precision bearings. In addition to this standard range, NSK can provide super precision bearings such as higher speed capability angular contact ball bearings, cylindrical roller bearings, radial ball bearings and double direction thrust ball bearings. A complementary range of linear guides and ball screws are also available in addition to mechatronic products such as Robot Modules™ and Direct Drive Megatorque Motors®.

Modern machine tool building is placing increasing demands on bearing performance in terms of higher rotational accuracy and speeds. NSK can meet these needs with its extensive range of super precision bearings which demonstrate the following distinct features:-

- Extreme accuracy
- High rotational speed
- Quiet and smooth running
- Minimum friction and heat generation
- Controlled rigidity

RHP SUPER PRECISION ANGULAR CONTACT BALL BEARINGS

Introduction

Since single row angular contact ball bearings have a contact angle they can sustain significant axial loads in one direction together with radial loads. Because of their design two opposed bearings or a combination of more than two bearings must be used.

Three series of super precision bearings are available, ISO series 19, 10 and 02, with preferred contact angles of 15° and 25° (fig. 1). The standard cage is laminated phenolic resin which is outer ring guided. The material and design provide for high speed and quiet running.

The many combinations of contact angle and preload allow precise selection to cope with the most arduous requirements of speed and capacity.

Fig. 1

Materials and Limiting Temperatures

The material for the rings and rolling elements is a carbon chrome bearing steel similar to BS970:534A99/535A99 or SAE52100. Components are through hardened and heat treated for stability and optimum life.

Maximum recommended operating temperature is 120°C for laminated phenolic resin caged bearings. If higher temperatures are required please consult NSK.

Dimensions

RHP Super Precision bearings are made in accordance with the International Standards Organisation's dimension plans. Full details are given in the bearing Tables 8-10 on pages 14-19.

The tolerances adopted conform to internationally recognised standards as shown in Table 1.

Precision grade P3 is an intermediate precision grade offering P2 runout tolerances with P4 external tolerances.

Table 1

RHP	P4	P3	P2
British Standards Institute (BS292)	EP7	-	EP9

International Standards Organisation (ISO 492)	Class 4	-	Class 2

High Point of Radial Runout

RHP Super Precision bearings are marked at the point of maximum ring thickness. The high point of radial runout is indicated by a small circle or burnished spot on the inner ring face (fig. 2a) and by a 'V' line on the outside diameter of the outer ring (fig. 2b). The bearings can then be mounted with these marks axially aligned with each other and opposed to the shaft or housing eccentricities in order to minimise assembled runout. The 'V' line on the outer ring indicates the direction of the contact angle.

Fig. 2a

Fig. 2b

Preload Levels

The ring faces of angular contact ball bearings are adjusted at manufacture so that, when the bearings are mounted in a back-to-back or face-to-face arrangement and clamped together, a predetermined force exists between them. To provide for a wide variety of applications a choice of standard preload levels are available:

- Suffix **EL** = **extra light** preload
- Suffix **L** = **light** preload
- Suffix **M** = **medium** preload
- Suffix **H** = **heavy** preload

The preload most frequently selected is “light” which is suitable for use in most applications where loads and speeds are not extreme.

As preload levels affect the maximum speed capabilities of pairs or sets of bearings, reference should be made to the section on ‘Limiting Speeds’, page 7.

Although four preload levels are offered as standard, other preloads can be supplied to fulfil unusual technical requirements. In such cases advice should be sought from NSK.

Universal Face Control

Super precision angular contact ball bearings are universally faced. This means that the inner and outer rings are the same width and the relative positions of the faces on both sides of each bearing are adjusted to give the required preload. The bearings can be mounted back-to-back or face-to-face without affecting the preload value. When mounted in tandem they will share load equally.

Pre-adjustment of the preload during manufacture eliminates the need to measure bearing face steps and to produce custom made spacers of differing widths to achieve the required preload.

Matching

Super precision angular contact ball bearings are supplied singly, in pairs and in multiple sets with matched bores and outside diameters. Matching improves load sharing when bearings are mounted close together.

The size variation of the bore and outside diameters of sets of bearings is generally $\frac{1}{3}$ rd of the tolerance. The bore and outside diameters of all bearings within a set will be within the specified size deviation tolerance, but will not necessarily be the same as each other.

Super precision bearings are graded (**fig. 3a**) and the deviation in microns from nominal size is marked on the face of each ring (**fig. 3b**). The grades are also marked next to the designation on the end of the box (**fig. 3c**).

Sets of Bearings

For heavily loaded applications, or where greater rigidity is required, it may be necessary to use a multiple bearing set. The composition of the set can be varied according to the loads to be imposed.

In certain cases specific configurations may be required as shown in **fig. 4**. Due to the special matching a ‘V’ line is included on the outside diameter of the bearings to ensure that they are mounted in the correct order. As standard the ‘V’ points in the direction of maximum axial capacity when the load is applied to the inner ring. The order of the bearings must not be changed, nor must they be interchanged between sets.

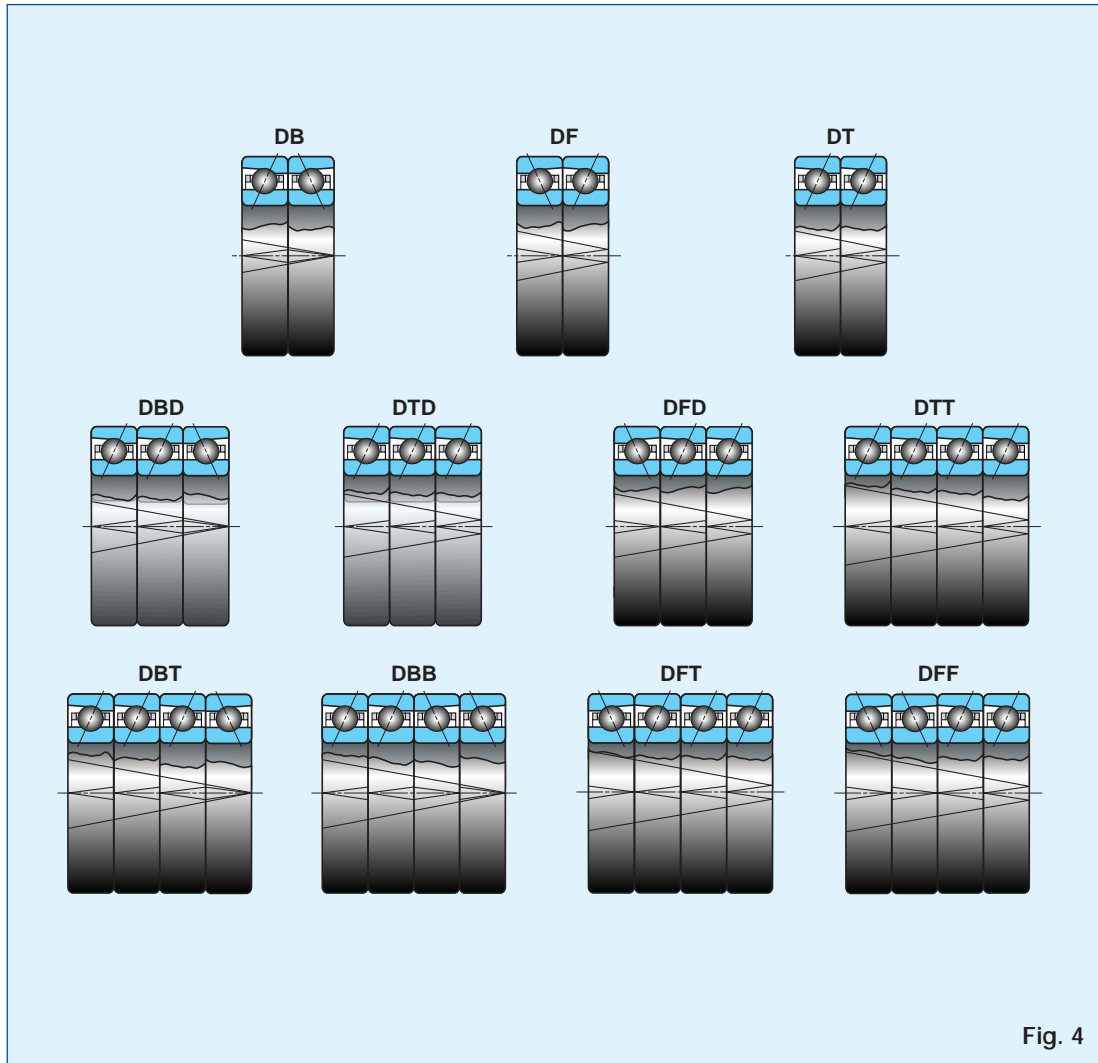

Fig. 4

Limiting Speeds

Limiting speeds are listed in the bearing tables. They should be regarded as a guide rather than an absolute figure since maximum speed can be affected by a variety of circumstances. They apply on condition that the bearings are operating under normal temperature conditions, are adequately protected from contamination and that the inner ring is the rotating member.

The tabulated speeds assume a light external load and are for single bearings under a spring preload which is adequate to maintain rolling contact without significant slip or spin between balls and raceways.

Speeds quoted for oil lubrication assume that oil/air lubrication is used and those for grease lubrication assume the use of a premium quality high speed synthetic grease. The use of other types of grease may influence the speed capability. Suggested factors for a selection of greases are shown in **Table 2** overleaf. To obtain the bearing speed multiply the tabulated speed by the appropriate factor.

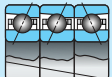

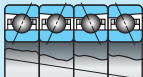

When bearings are used as back-to-back pairs or sets the recommended limiting speeds are reduced in accordance with **Table 3** overleaf. If the bearings are mounted face-to-face the limiting speeds are reduced by a further 50%. For spring loaded tandem pairs the speed factor is 0,95

Table 2

Grease Type	Factor
Klüber Isoflex NBU15	1,00
Klüber Isoflex Super LDS18	0,83
Klüber Isoflex Topas NB52	0,83
Klüber Isoflex NCA15	0,83

Table 3

	Pairs DB 	Sets of Three DBD 	Sets of Four DBB 
Extra light	0,85	0,70	0,65
Light	0,80	0,65	0,60
Medium	0,60	0,50	0,45
Heavy	0,40	0,35	0,30

Note: The speed factor for spring loaded tandem pairs is 0,95

Lubrication

A bearing is lubricated for three main reasons:

- (1) to minimise any sliding friction that occurs between raceways, rolling elements and cage,
- (2) to provide corrosion protection for the accurately ground and polished surfaces,
- (3) to dissipate generated heat.

To ensure the successful operation of a spindle assembly, the importance of correct lubrication cannot be over emphasised. Two basic types of lubricant are in general use; oil and grease.

Oil Lubrication

Extremely small amounts of oil are usually enough to lubricate a bearing satisfactorily. Any excess oil increases the drag forces during rotation and energy is dissipated as heat.

As speed increases precise control over the amount of oil is needed. Experience has shown that this is best achieved by an 'oil/air' system in which accurately metered amounts of oil are carried in an airstream and injected into the bearing. The airflow also helps to exclude contaminants from the spindle. The optimum flow may need to be determined experimentally.

A guide to the delivery rate for normal operating speed can be estimated from the following:

$$V = 0,15 \times d \times B \text{ (mm}^3\text{/hour)}$$

A guide to the flow rate for high speed operation is:

$$V = 7 \times 10^{-6} \times B \times D_m \times N \text{ (mm}^3\text{/hour)}$$

Where V = oil flow rate (mm³/ hour)
 d = bearing bore (mm)
 B = bearing width (mm)
 D_m = mean bearing diameter (mm)
 N = maximum spindle speed (rpm)

The delivery can then be increased or decreased until the minimum operating temperature is achieved.

For normal operating speeds nozzles parallel to the spindle axis provide adequate lubrication (fig. 5a). For constant high speed operation nozzles that are angled to the spindle axis have proven advantageous (fig. 5b).

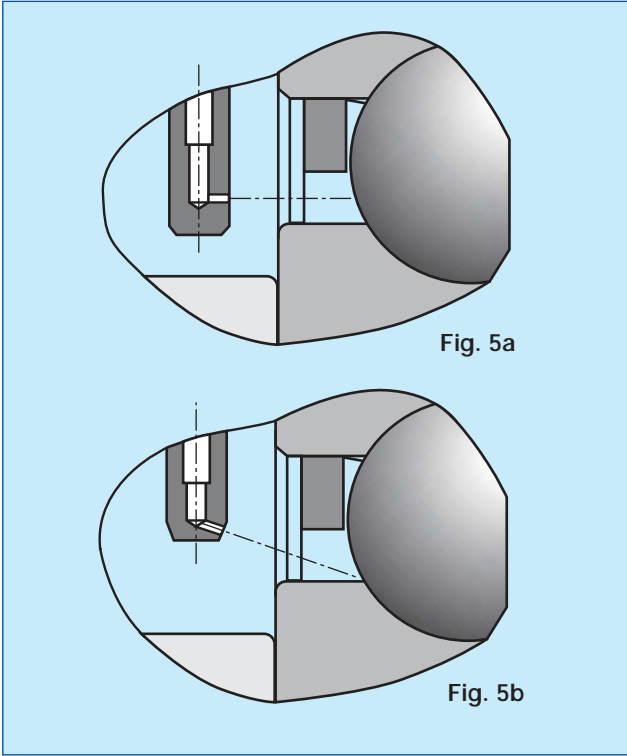

Fig. 5a

Fig. 5b

To use such a nozzle requires more detailed knowledge of the bearing geometry and this can be obtained from NSK.

Adequate drainage must be provided to prevent a build up of oil inside the spindle and around the moving parts which could generate additional heat and cause subsequent bearing failure.

The oil should be filtered before filling the lubricator, the maximum particle size should not exceed 5µm.

Oil Type

A good quality lubricant must be selected to minimise oxidation and foaming. It must be clean and free from moisture to reduce wear. Its viscosity should be just high enough to allow an effective elasto-hydro dynamic (EHD) film to be formed in the pressure zones of the bearing. Lubricant viscosity varies rapidly with temperature and the probable operating temperature should be considered when selecting the type of oil.

Many spindles run over a wide speed range and some compromise may be necessary.

Grease Lubrication

The main advantages of grease lubrication are that it provides an economical method of achieving minimal lubrication and maintenance free operation over long periods. It also eliminates the need for an external lubrication system, permits the use of simple closures and provides some degree of protection against the ingress of contaminants. However, grease lubrication lacks the cooling effect and constant lubrication replenishment provided by oil/air. Consequently bearing speeds with grease lubrication are lower.

The grease type must be selected according to the operating conditions. It has been found that many applications can be satisfied with a selection from the greases in **Table 2**, page 8.

Whichever type of grease is selected, care must be taken in applying the correct quantity and space should be provided to accommodate any excess grease expelled during running.

For low and medium speed spindles (<60% of the maximum speed of the bearing set) the recommended grease quantity is 30% of the internal volume, for higher speeds this can be reduced to 20% and for very high speed spindles (>80% of the maximum speed of the bearing set) 10-15% is recommended. Internal volumes are given in the bearing **Tables 8-10** on pages 14-19. If too much grease is packed into the bearing abnormal heat generation occurs causing the grease to deteriorate. To avoid this risk it is necessary to 'run in' spindles for a sufficient time to distribute the grease. It is recommended that the spindle is progressively run up to full speed in a series of suitably sized speed increments whilst monitoring the temperature. The temperature should be allowed to stabilise at each speed increment before increasing the speed. If the temperature reaches 70°C the spindle should be stopped and allowed to cool before restarting it.

Table 11

Accuracy of Associated Components

Super precision ball bearings have relatively thin rings and will take up the shape of the mating shaft or housing, thus transferring any errors in form to the bearing raceway. Abutment faces on the associated parts must be square to the axis of the shaft, or the bearing rings may be misaligned, resulting in increased runout and higher running temperatures, particularly on high speed spindles.

To obtain satisfactory results errors of form should not exceed the values given in **figs. 6 and 7**, and **Tables 11 and 12**.

The housing should be robust so that when it is attached to the machine it is not distorted. When the inner ring is the rotating member, bearings are generally mounted with an interference fit on the shaft. A transition fit should be selected for the housing for locating bearings and a clearance fit selected for sliding bearings.

Recommended shaft and housing tolerances are given in **Tables 13 to 15**.

		P2 mean	0,5T	0,5T	0,5T	0,5T	1,9T	3T	3,2T	3,8T	-

T = interference fit

These shaft limits apply when the inner ring rotates and the load line is constant in direction. For other conditions consult NSK.

Tighter shaft fits may be necessary to avoid loosening at speeds over $1.8 \times 10^6 D_m N$, please consult NSK for advice since this will affect the preload.

Table 17

Outer Ring Tolerances in μm			18	30	50	80	120	150	180	250	315
Nominal outside diameter D (mm)	over including		30	50	80	120	150	180	250	315	400
Deviation of mean outside diameter Δ_{Dmp}	P4 & P3 (+0)	P4 & P3	-5	-5	-5	-7,5	-9	-10	-10	-13	-13
		P2	-3,8	-3,8	-3,8	-5	-5	-6,4	-7,5	-7,5	-10
Radial runout of an assembled bearing outer ring K_{ea}	P4 P3 P2	P4	4	5	5	5	7	7,5	10	10	13
		P3	2,5	2,5	3,8	5	5	5	6,4	6,4	7,5
		P2	2,5	2,5	3,8	5	5	5	6,4	6,4	7,5
Outer diameter runout with reference face S_{D}	P4 P3 P2	P4	4	4	4	5	5	5	7	7,5	10
		P3	1,3	1,3	1,3	2,5	2,5	2,5	3,8	3,8	6
		P2	1,3	1,3	1,3	2,5	2,5	2,5	3,8	3,8	6
Raceway groove runout with reference face S_{ea}	P4 P3 P2	P4	5	5	5	5	7	7,5	10	10	13
		P3	2,5	2,5	3,8	5	5	5	6,4	6,4	7,5
		P2	2,5	2,5	3,8	5	5	5	6,4	6,4	7,5

The width deviation (Δ_{Cs}) and width variation (V_{Cs}) for an outer ring is the same as that of the inner ring (Δ_{Bs} and V_{Bs}) of the same bearing.

RHP Super Precision Angular Contact Ball Bearings

7 0 10 C TR DU L P3

7	TYPE	7	Single row angular contact ball bearing		
0	DIMENSION SERIES	RHP 9 0 2	ISO 19 10 02		
10	BORE CODE	00 - 10mm 01 - 12mm 04 upwards multiply by 5 to obtain bore size in mm	02 - 15mm 03 - 17mm		
C	CONTACT ANGLE	C A5	15° 25°		
	CONSTRUCTION¹	● SN24	Normal type (steel ball) Ceramic ball type		
TR	CAGE MATERIAL & LOCATION	TR	Outer ring guided phenolic cage		
DU	GROUPING	SU DU, DB, DF, DT 3U, DBD, DFD, DTD QU, DBB, DFF, DBT, DFT	Single universal Paired unit Triple set Quad set		
L	PRELOAD	EL L M H	Extra light Light Medium Heavy	P**, CP** A**, CA**	Special preload Special axial clearance
P3	PRECISION GRADE	RHP P4 P3 P2	ISO Class 4 Dimensional accuracy P4, running accuracy P2 Class 2	ABEC 7 9	

- Denotes standard feature, no indicator necessary
- ** Denotes mean figure given in μm
- Denotes possible reference indicator may appear
- ¹ In the old RHP design, construction is before the contact angle
